

Concepts of Object Oriented Programming

- 
- **Programming Paradigm**
 - **Procedure oriented programming paradigm**
 - **Object oriented programming paradigm**
 - **Advantages of OOPs**
 - **Basic concepts of OOPs**

Programming paradigm

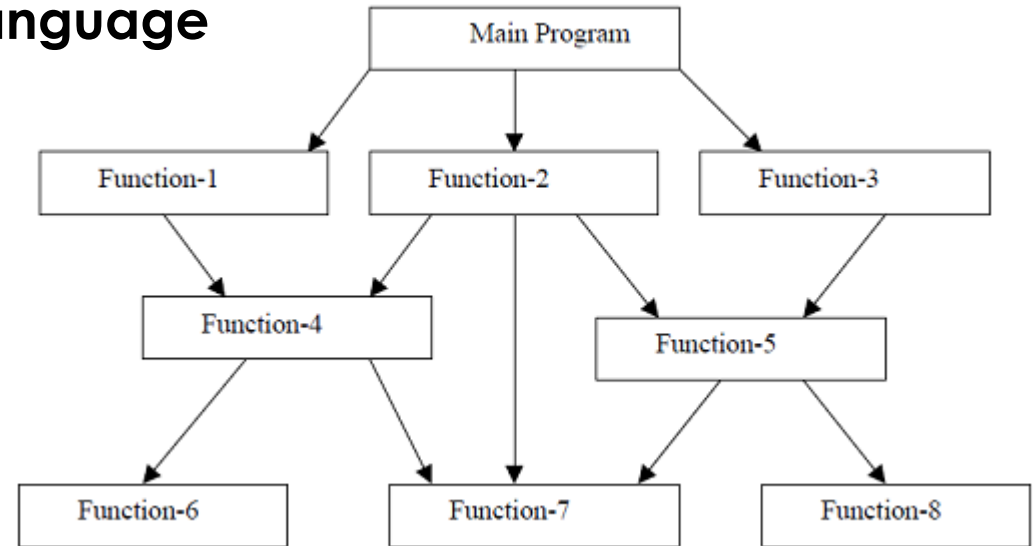

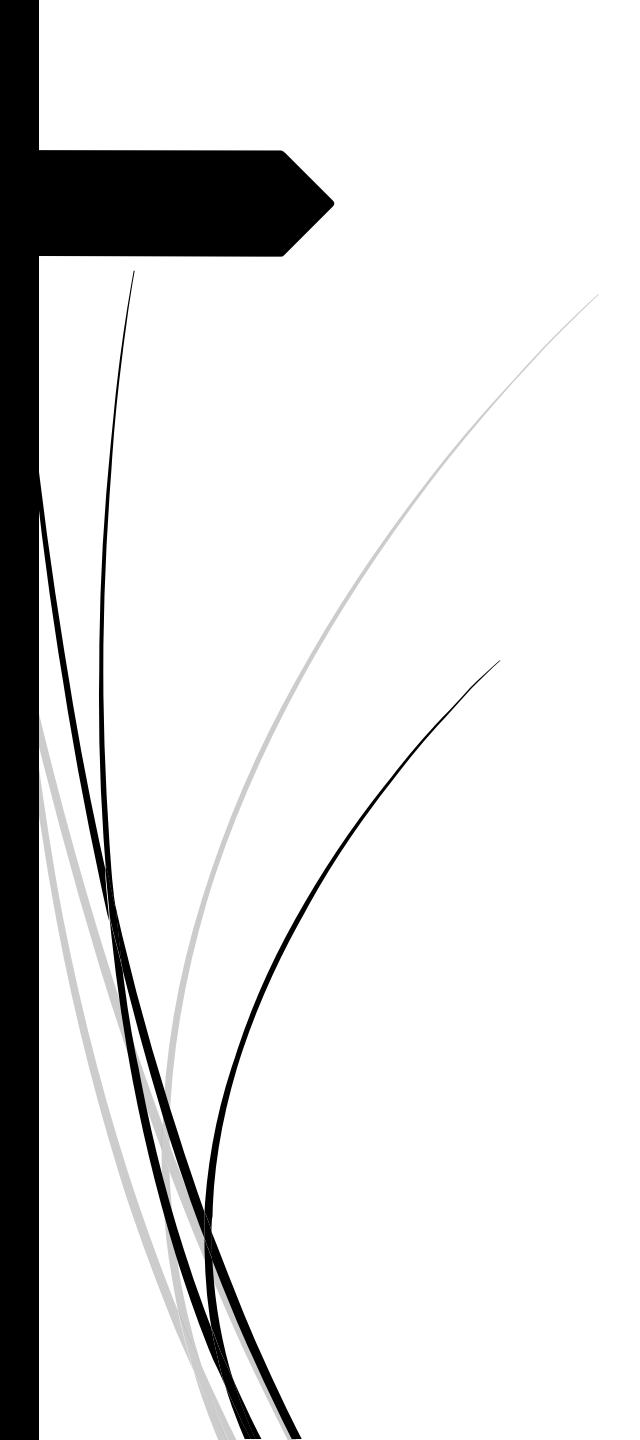

■ Programming paradigm

- Def : Programming paradigm are a **way to classify** programming languages according to the **style** of **computer programming**
- Some paradigm gives more important to the **procedure**, others gives more important to the data
- The term paradigm used for **reduce** the **complexity** of the programming language

➤ Procedure oriented Programming paradigm

- It specifies a **series** of **well structured steps** and **procedure** to compose a program
- It contain a **systematic** order
- Also called **top-down** language

- 
- **Complex** type programming paradigm
 - For reduce complexity : use **functions** and modules
 - Eg : C, Pascal, Basic, Fortran

➤ Reason for increase the complexity

- Give important to **procedure** than data
- to **add** a new **data item**, should rewrite the program
- Create a new **data-type** is difficult (no user defined datatype)
- Data and functions are treated as **separately**

Data

Function

➤ Object oriented Programming paradigm

- It eliminate the drawback of POP Paradigm
- **Bottom** to **up**
- Data and functions are treated as a **single unit**

Object

➤ Advantages of OOPs

- **Modularity** (divide Large program by module)
- Allow data **abstraction** (Hide / Protect data from user)
- Good for defining abstract data-types
- code **re-usability**
- **Real world** data entities can easily created
- Support to create new **data-types** (User defined)

Basic Concepts Of OOPs

➤ Basic concepts of OOPs

- Object
- Class
- Data Abstraction
- Data Encapsulation
- Modularity
- Inheritance
- Polymorphism

➡ Object

- ➡ Anything around us can be treated as an **object**
- ➡ It have **properties** and **behaviours**

- ➡ The object **combines data** and **function** as a **single unit**

Properties

Behaviours

Real-world Object

Data

Function

OOP Object

- The function inside the object is called member function
- And data is called member

- Object define inside the class

➡ Classes

- ➡ Class is a **user defined** data type
- ➡ Class is **collection** of **objects** with similar attributes(properties)

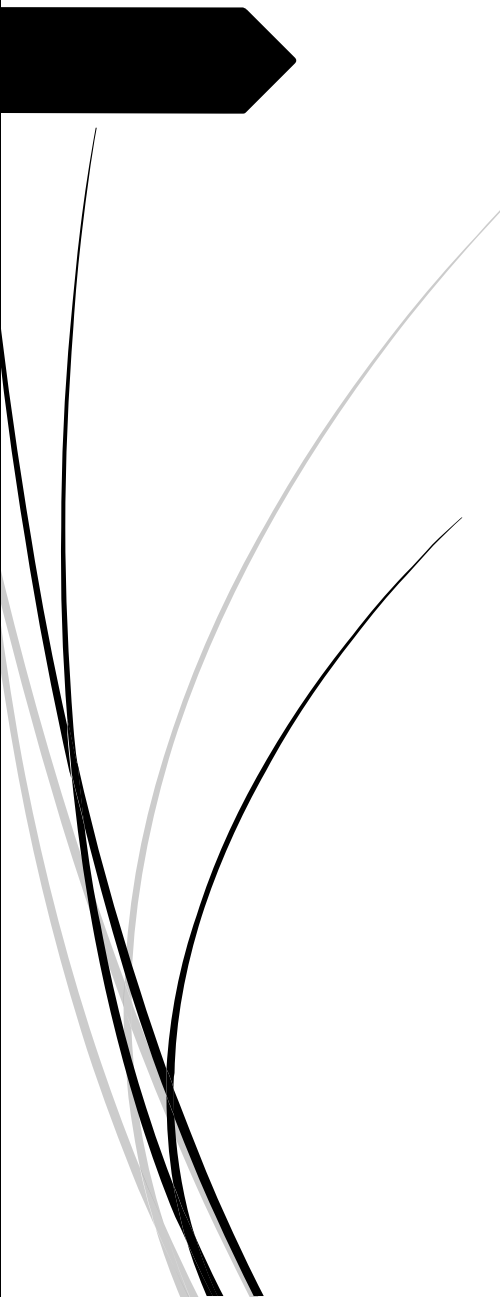

- ➡ Class declare using the keyword **“class”**
- ➡ Class is a **blueprint** of **objects**

➤ Syntax

```
class class_name
{
    private:
        variable declarations;
        function declarations;
    public:
        variable declarations;
        function declarations;
};
```

```
class Student
{
    public:                // Access specifier
        string name;      // Data Members

        void display()    // Member Functions()
        {
            cout << "Student Name is: " << name;
        }
};

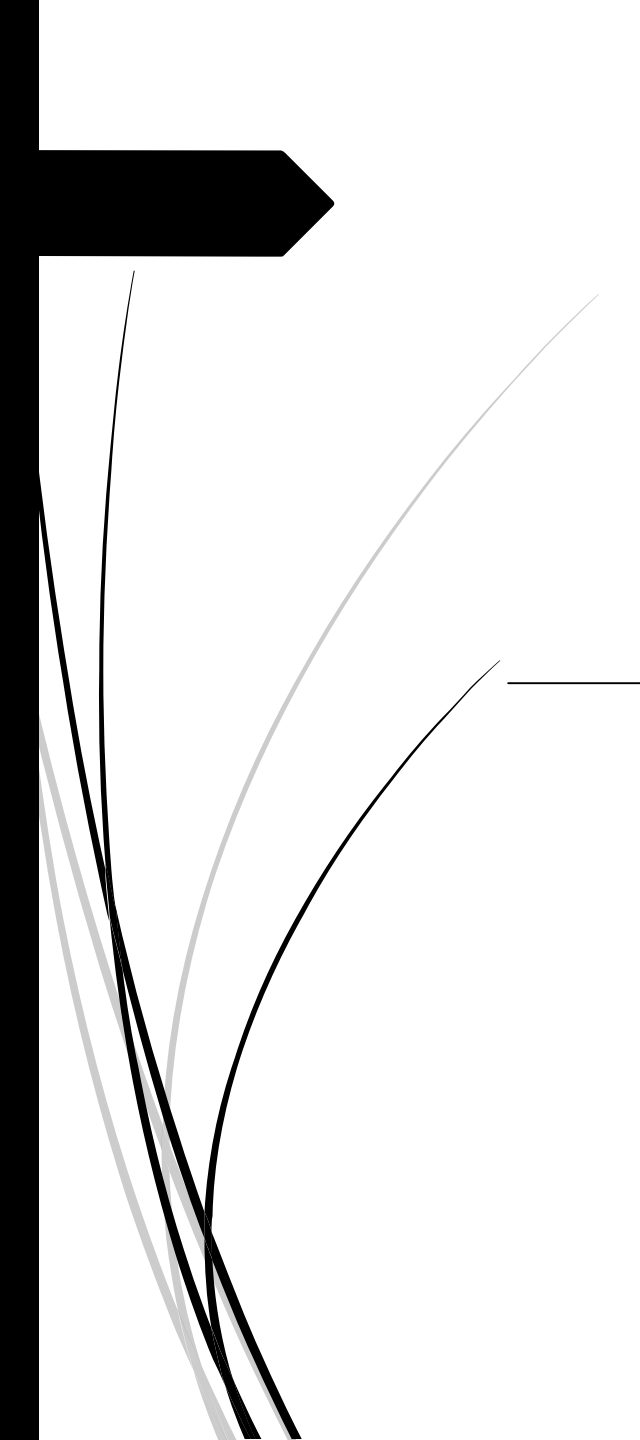

int main()
{
    Student obj;          // Declare an object of class

    obj.name = "Appu";    // accessing data member
    obj.display();        // accessing member function
}
```

➤ Data Abstraction

- It is an essential features of OOP
- **Hiding** details from out standers
- It gives the output without showing the details
 - **Public** : visible in main function (not hide)
 - **Private** : only visible inside the class (hide)
 - **Protected** : only visible in derived classes (hide)

```
class Student
{
    public:
        float mark;

        void display()
        {
            cout << "Student Mark is: " << mark;
        }
};
```

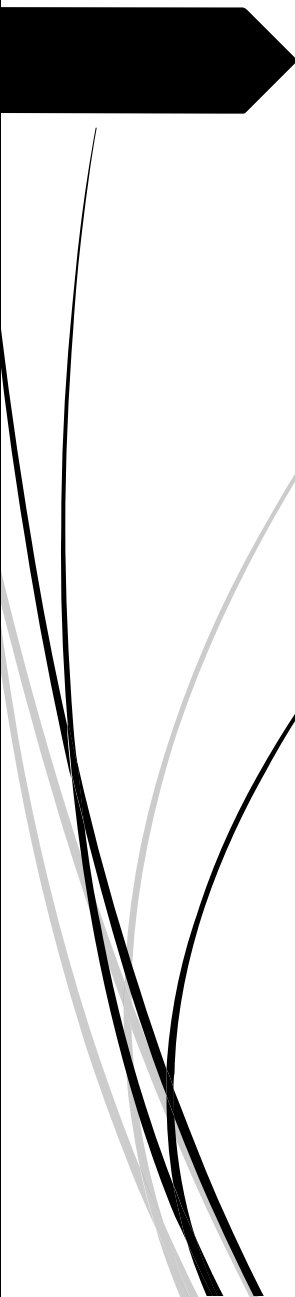

```
class Student
{
    private:
        float mark = 35;

    public:
        void display()
        {
            cout << "Student Mark is: " << mark;
        }
};
```

➤ Data Encapsulation

- **Binding** of **data** and **functions** together
- Keeps both data and function safe from main program / outside interface
 - Private : only visible inside the class (hide)
 - Protected : only visible in derived classes (hide)

```
class Student
{
    protected:
        float mark = 0;
};
```

```
class Appu : public Student
{
    public :
        void english(float m)
        {
            mark = m;
        }

        void display()
        {
            cout << "English Mark is: " << mark;
        }
};
```

```
int main()
{
    Appu obj;

    obj.english(31);
    obj.display();
}
```

➤ Modularity

- All programs are written / divide into **modules**
- It reduce the **complexity** of program
- And each module can be used for another project (code **re-usability**)
- Each module execute when **call** the **module** using **function name**

Main ()

20 line program set

10 line program set

50 line program set

5 line program set

10 line program set

Main()

Total = 95 line program

Module 3

Module 1

Module 4

Module 5

Main ()

Module 1
Module 2
Module 3
Module 4
Module 5

Module 2

Module 3

The diagram illustrates a sequence of module calls. A black arrow points from the left towards the 'Main ()' block. From 'Main ()', a series of curved lines lead to five yellow boxes labeled 'Module 3', 'Module 4', 'Module 1', 'Module 5', and 'Module 2'. The 'Main ()' block itself contains a list of module calls: 'Module 1', 'Module 5', 'Module 1', 'Module 4', and 'Module 1'.

Module 1

Module 4

Module 5

Main ()

Module 1
Module 5
Module 1
Module 4
Module 1

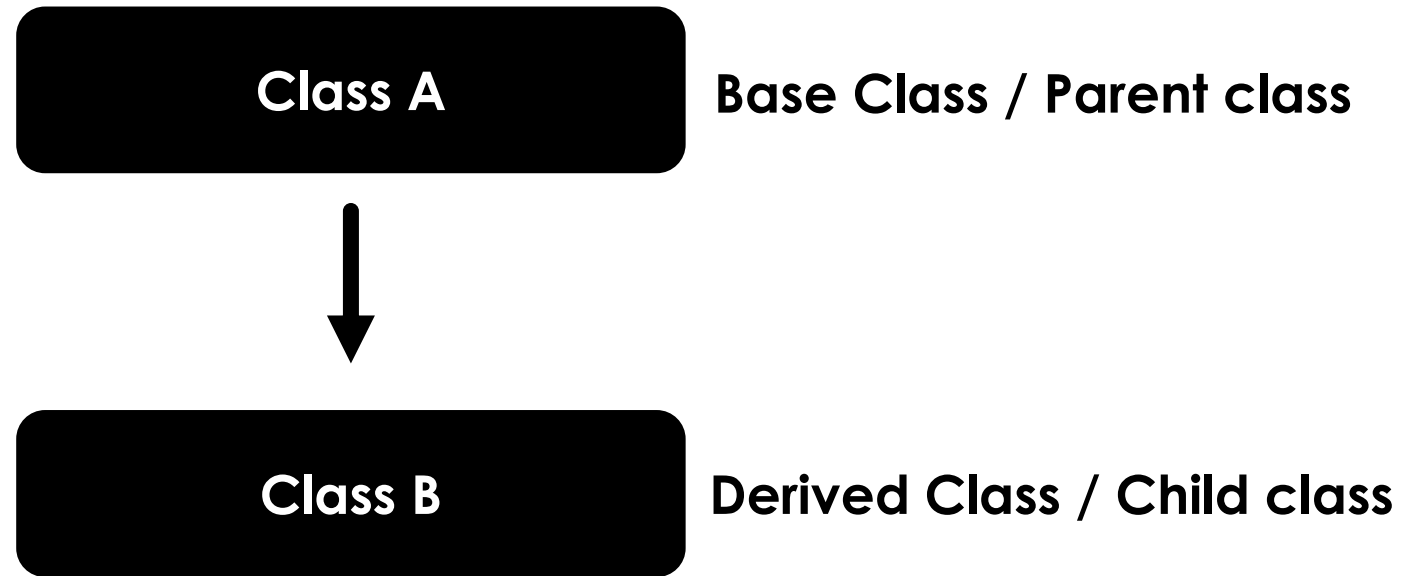

Module 2

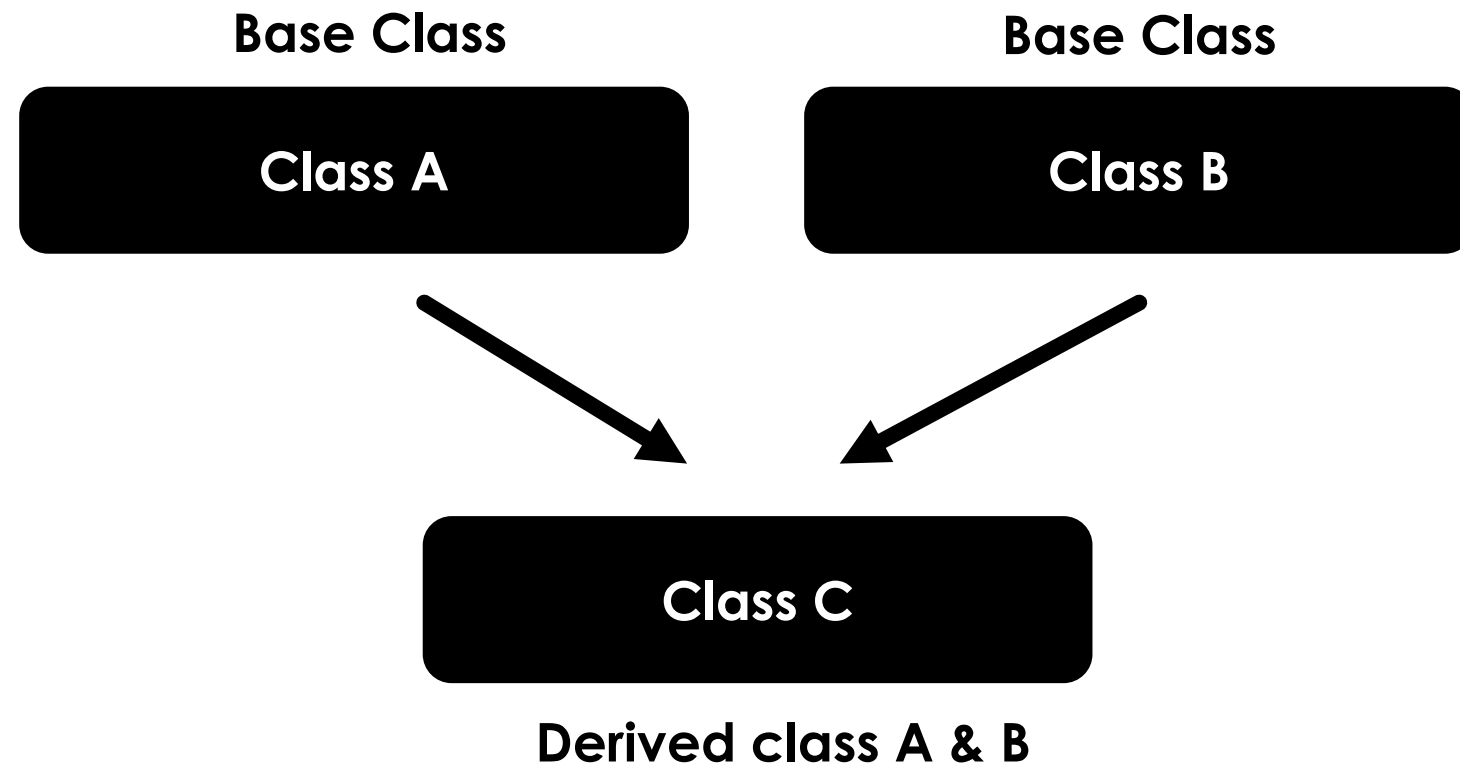

➤ Inheritance

- One class derived from another one
- One class showing the property of another class
 - **Single** Inheritance
 - **Multiple** Inheritance
 - **Hierarchical** Inheritance
 - **Multilevel** Inheritance
 - **Hybrid** Inheritance

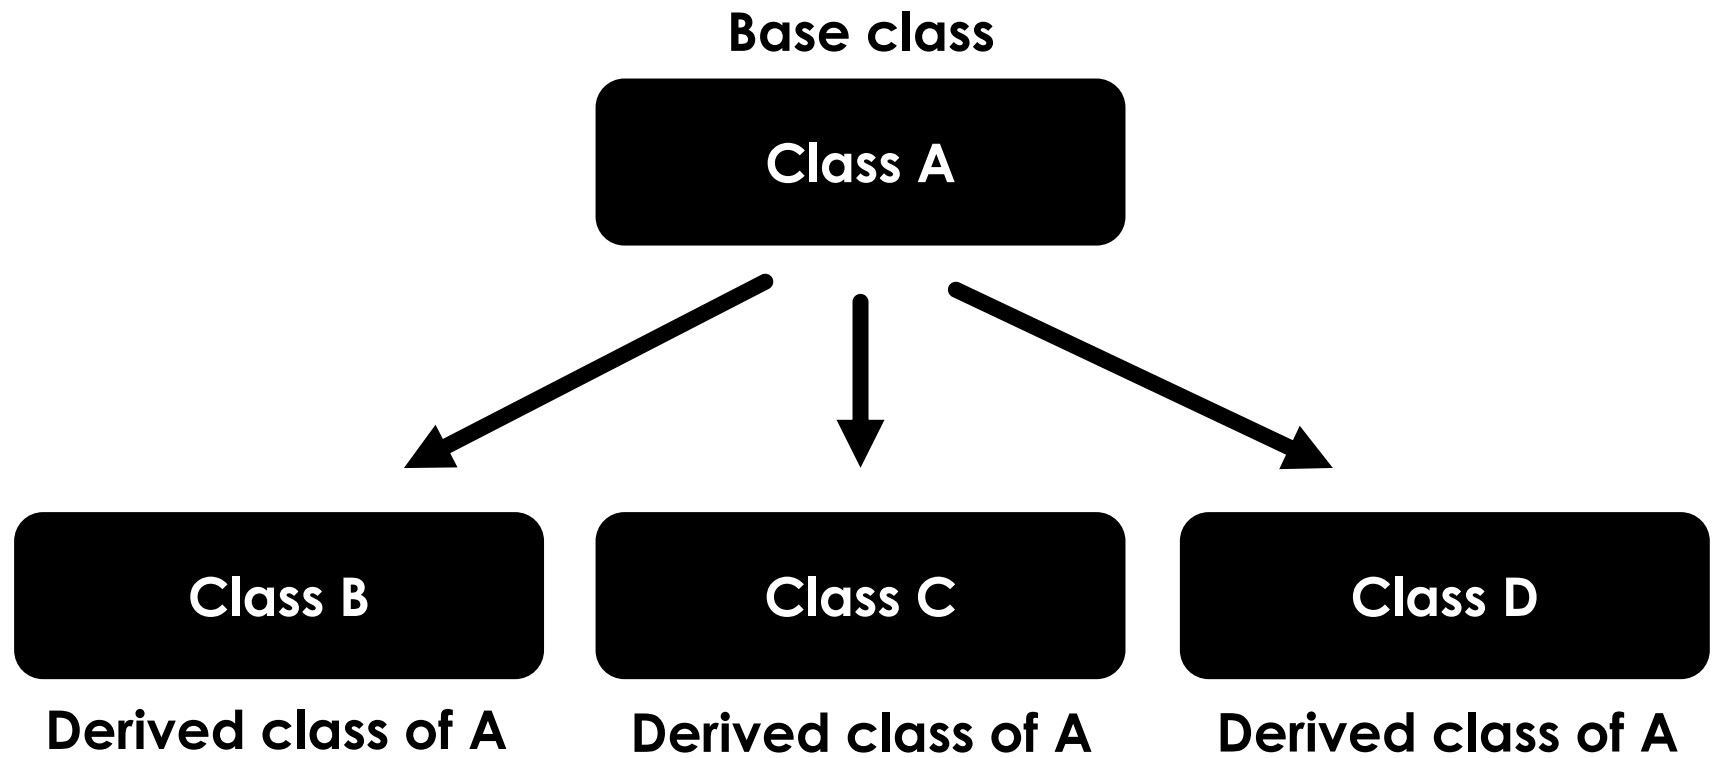

➡ Single Inheritance

➡ Multiple Inheritance

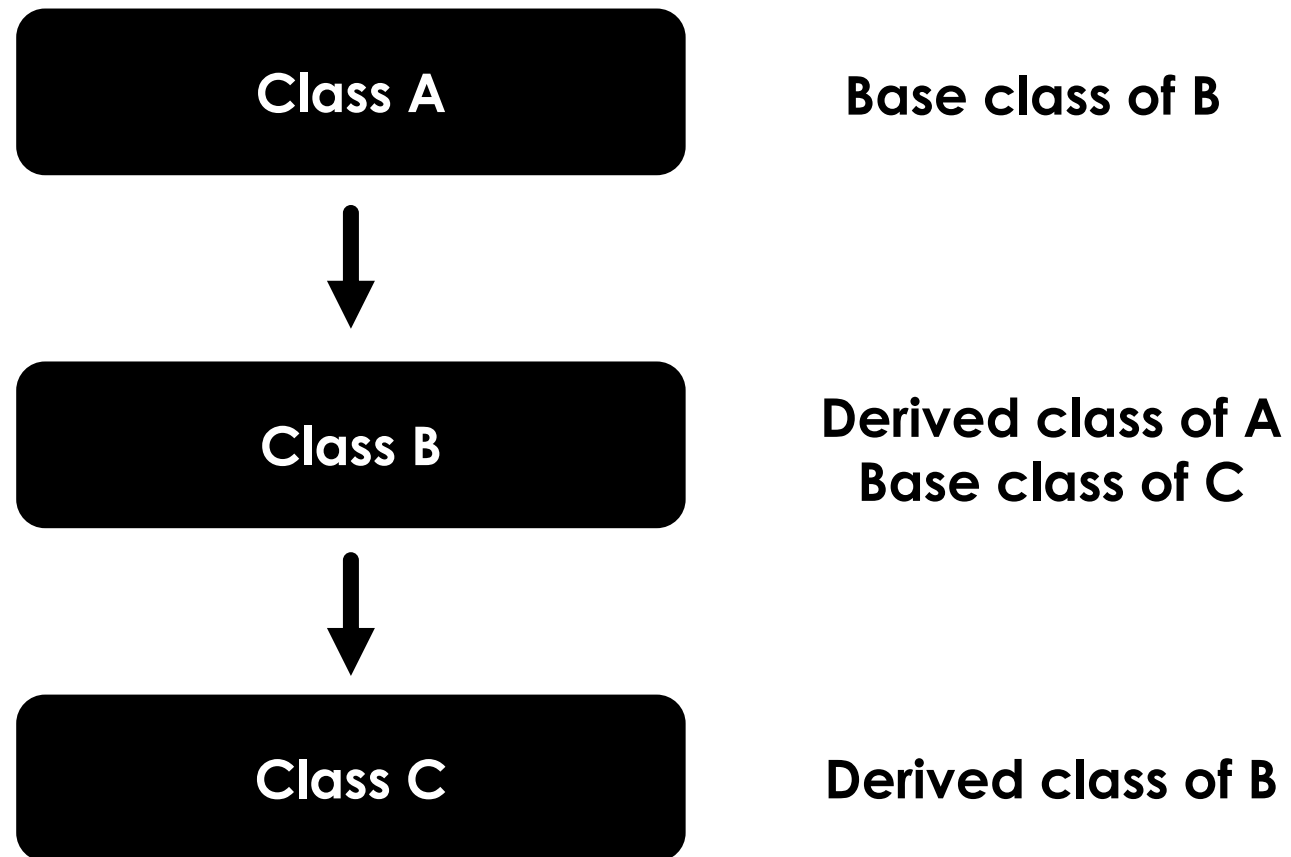

➡ Hierarchical Inheritance

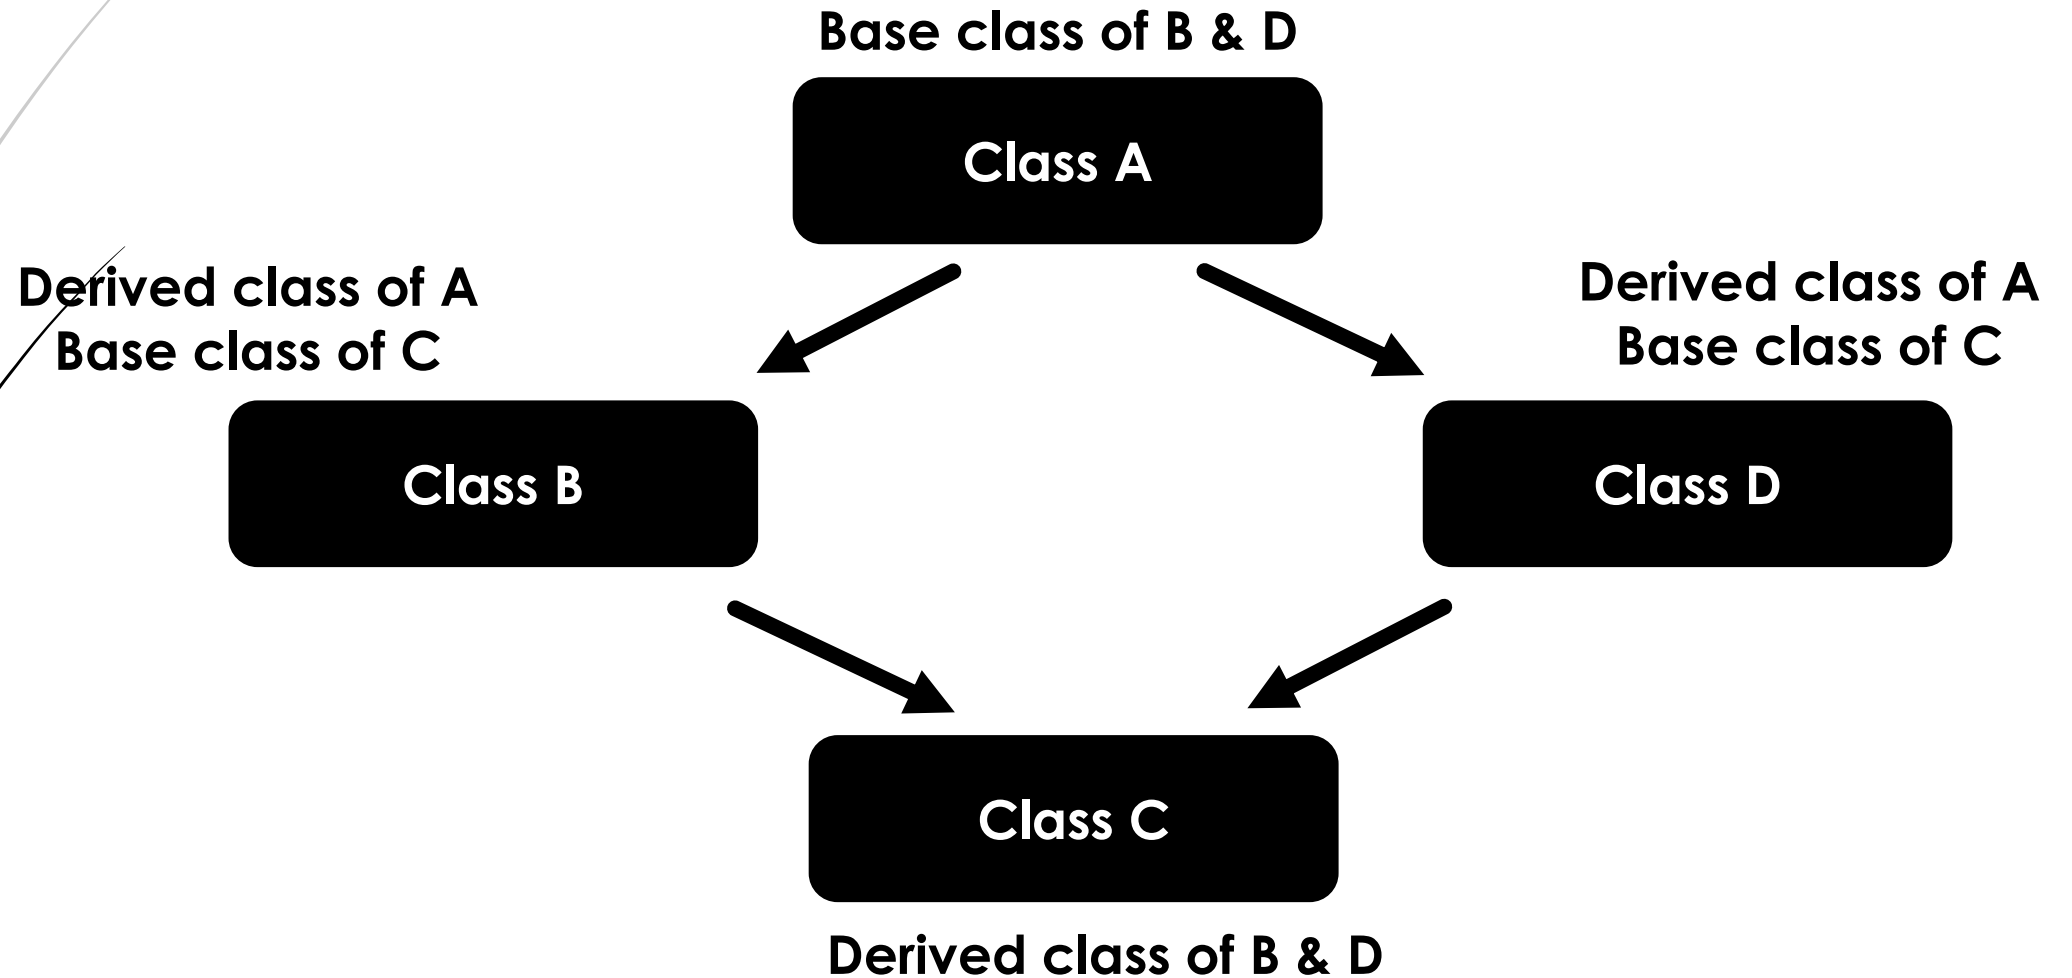

➡ Multilevel Inheritance

➡ Hierarchical Inheritance

➤ Polymorphism

- One **function** or **operator** or any other **symbols** can be used for **different use** called polymorphism

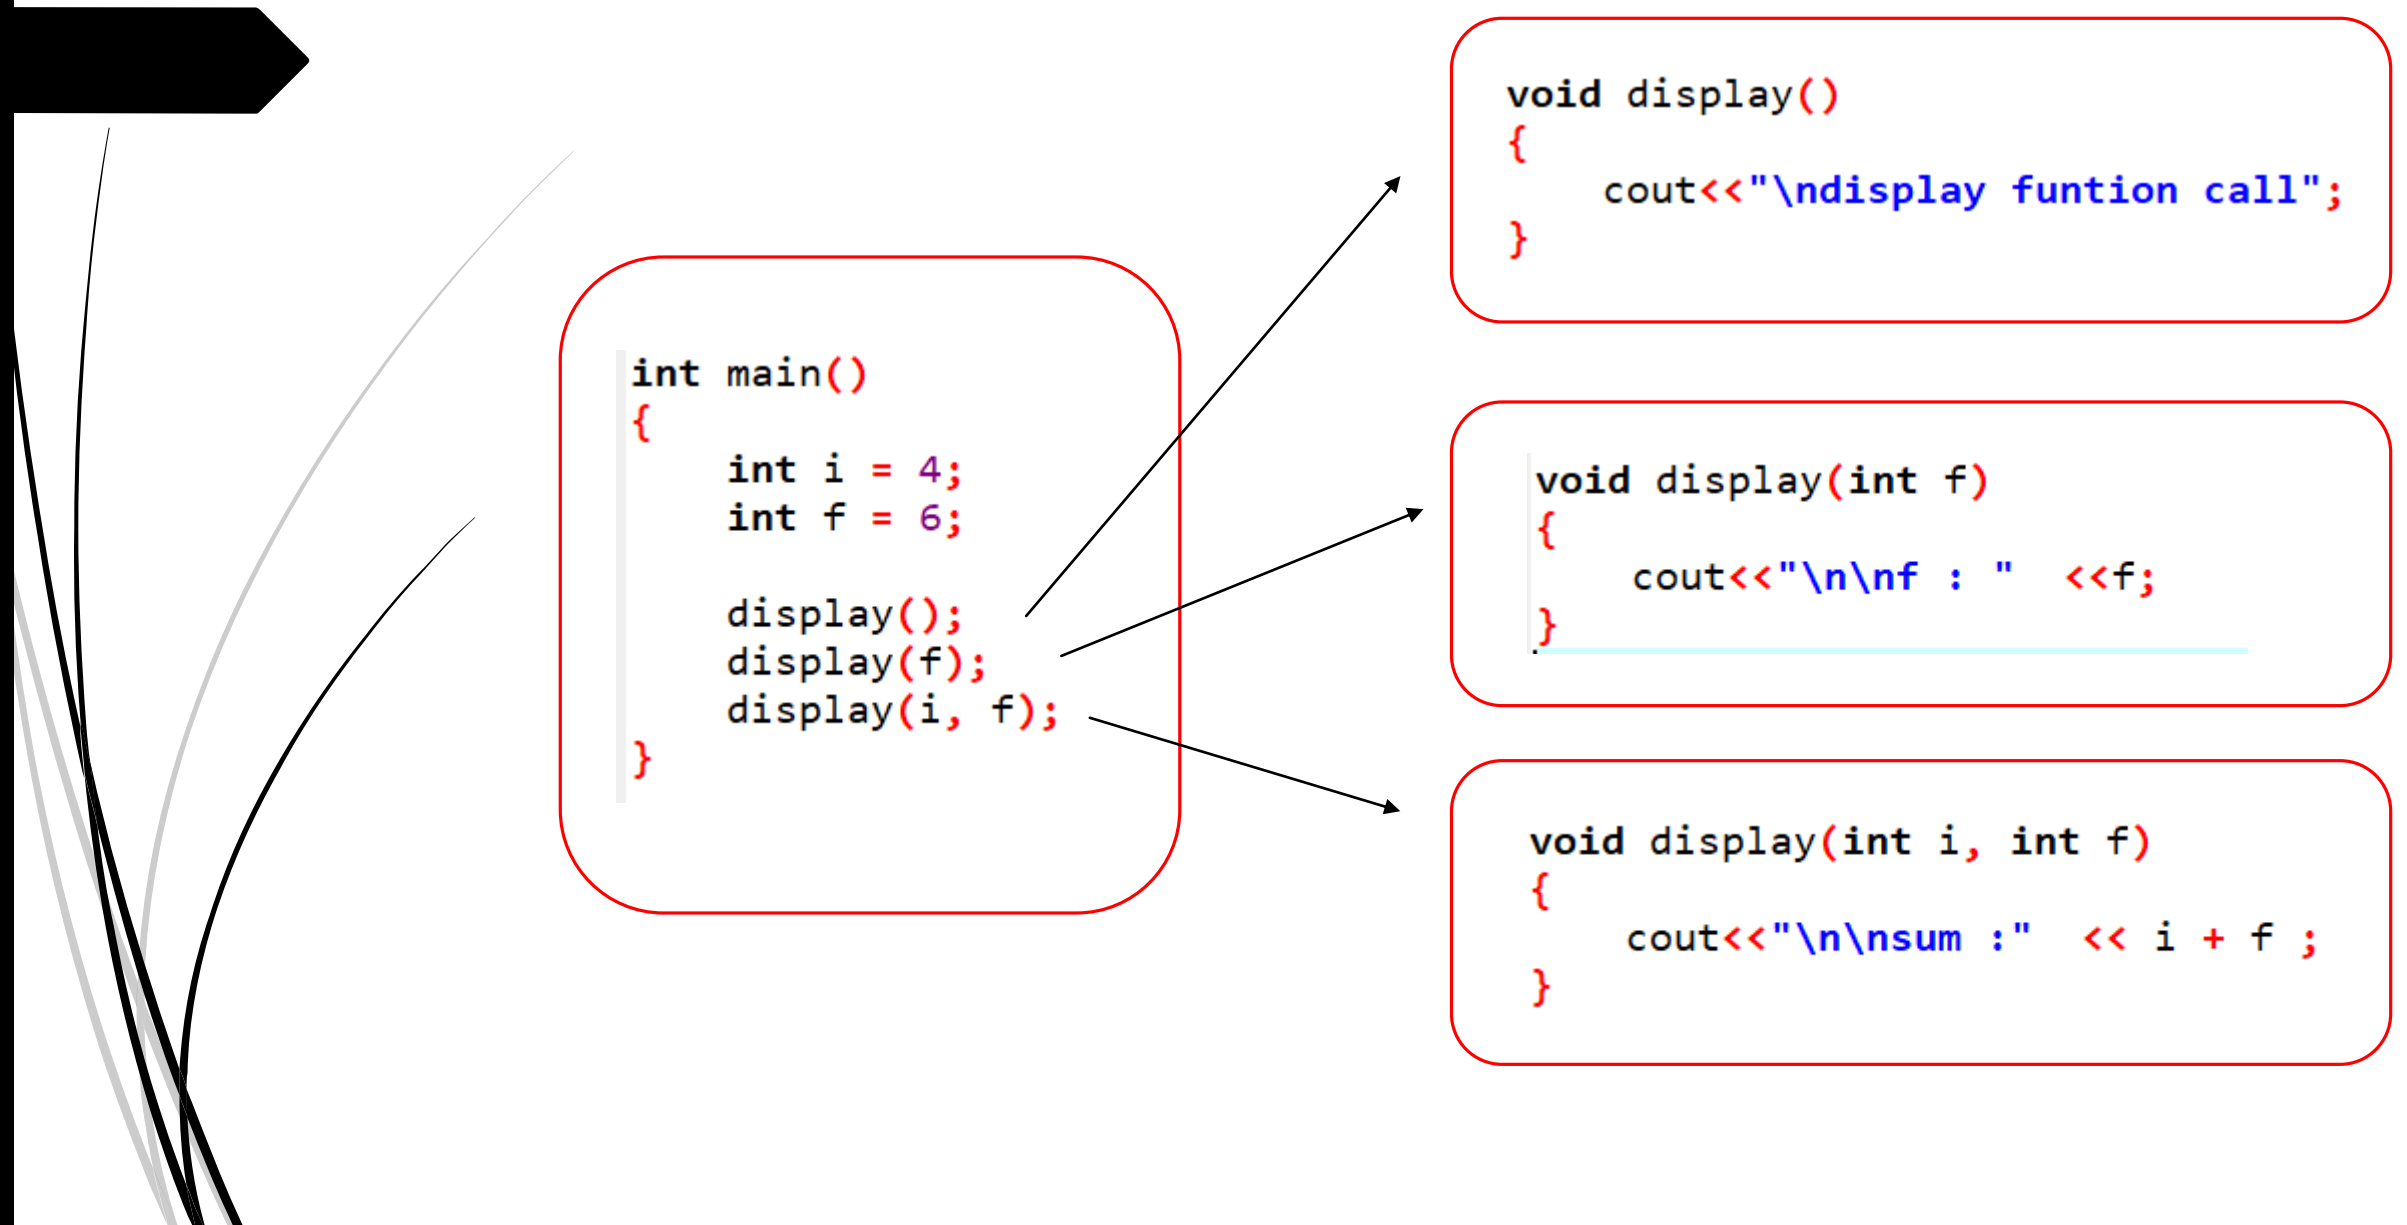

- **Operator overloading**

- One operator is used for more than one operation is known as operator overloading

- Ex : + (4 + 6) “hello” + “world”

- **Function overloading**

- One Function name is used for more than one functions is known as function overloading

The diagram illustrates function calls from a `main` function to three different `display` functions. On the left, a black arrow points to the `main` function box. From the `main` box, three arrows point to the right: one to the first `display` box (from `display();`), one to the second `display` box (from `display(f);`), and one to the third `display` box (from `display(i, f);`). The `main` box and the three `display` boxes are each enclosed in a red rounded rectangle.

```
int main()
{
    int i = 4;
    int f = 6;

    display();
    display(f);
    display(i, f);
}
```

```
void display()
{
    cout<<"\ndisplay funtion call";
}
```

```
void display(int f)
{
    cout<<"\n\nf : " <<f;
}
```

```
void display(int i, int f)
{
    cout<<"\n\nsum :" << i + f ;
}
```
